Abstract

Existing movie recommendation systems often rely on complex algorithms such as collaborative filtering and content-based filtering across vast datasets, sometimes leading to recommendations that, while broadly aligned with user preferences, lack specificity or highlight less critically acclaimed films. These systems frequently neglect the crucial aspect of immediate accessibility, requiring users to separately search for streaming availability. Our proposed system addresses these shortcomings by prioritizing a user-centric approach. We focus on direct genre selection by the user as the primary filter, ensuring recommendations are precisely within desired categories. Subsequently, we integrate reputable movie rating sources (e.g., IMDb, Rotten Tomatoes) and sort the results by rating, guaranteeing users are presented with high-quality options.

A key differentiator is the seamless integration of streaming availability information directly within the recommendation output. This eliminates the need for external searches and significantly enhances user experience. By combining explicit genre selection, rating-based prioritization, and readily available streaming information, our system offers a more focused, efficient, and user-friendly movie discovery experience. This approach provides a balance between personalized recommendations and curated selections of high-quality, readily accessible films.

Key Elements: Genre filtering, rating-based sorting, streaming availability integration, user centric design.
